Part 3 | Stated values and disclosure alignment

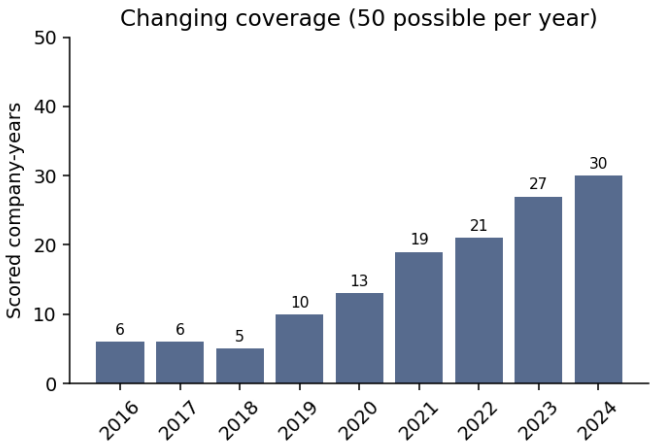

Provisional analysis of archived values pages and DEF 14A proxy statements, 2016-2024.

Coverage: 137 of 450 company-years (30.4%), across 36 of 50 companies. There are 96 adjacent-year score comparisons. Missing and ineligible records receive no score. Historical values-page availability is the principal constraint.

What the score means. Nine shared themes connect the two sources. Each stated theme receives equal weight; proxy themes are weighted by their dictionary mention rates. Cosine similarity measures how closely those profiles line up, from 0 (no overlap) to 1 (proportional profiles). It does not measure how many promises were fulfilled, or whether a company behaved authentically.

Observed results: mean 0.546, median 0.594, range 0.072-0.897. Giving each represented company equal weight yields a mean of 0.553. These are descriptive summaries of the available sample.

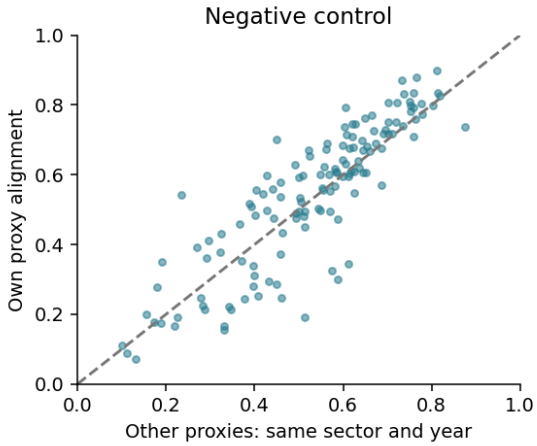

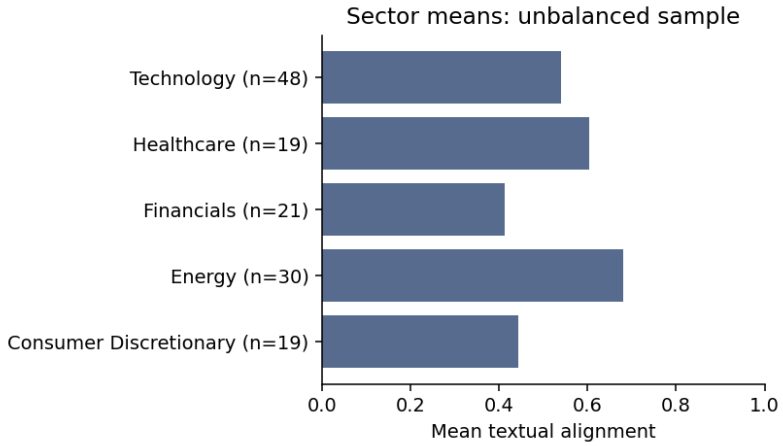

Variation. The output tables provide year, sector and company summaries, together with adjacent-year changes. The sample grows over time, so a change in the yearly mean may reflect which companies are observed. Sector comparisons also mix different firms and years; they are not rankings of corporate virtue.

The variance of observed company means is 0.0370; average squared deviation within companies is 0.0095. Unequal years per company and single-observation firms prevent interpreting these as clean between/within variance components.

Validity checks and practical limits

Negative control: each stated-values profile was also compared with other companies' proxies in the same sector and year. Its own proxy scored only 0.015 higher on average. This small separation suggests substantial generic vocabulary and limited company-specific discrimination. It is a descriptive diagnostic, not a significance test or validation of authenticity.

Sensitivity: log-transformed rates give mean 0.579; removing integrity and inclusion gives 0.612. Excluding specifically scope-flagged values sources leaves 99 observations, mean 0.543. Only 11 archive captures precede or coincide with proxy filing. These alternate definitions/subsamples answer different questions and do not eliminate bias.

Main threats. (1) Sparse, uneven historical coverage limits representativeness. (2) Values and recruitment pages differ from proxies, which mix management claims, shareholder proposals, compensation and required governance. (3) Model-coded theme presence and dictionary frequencies have different errors; synonyms, negation and repeated boilerplate matter. (4) Capture dates, filing dates and corporate entity changes may misalign observations. (5) Both sources describe communications, not independently observed conduct.

Checks completed: panel keys, theme vocabulary, rate/count consistency, missing-data treatment, mathematical edge cases, sensitivity and negative-control calculations. Source URLs and provenance are retained. The project owner confirmed completing source review without further corrections, including retention of the three diagnostic cases. These checks remain exploratory and cannot establish actual organizational behavior.

Use: treat this as an exploratory textual alignment index. Preserve the limitations in any presentation or subsequent analysis. Reproducible code, input hashes and detailed result tables accompany this summary.
